

Building Linux for the ADMXRC7Z1/2

Introduction

This guide describes how to build the Open Source Embedded Linux distribution "Poky" using the Yocto build system, and "Das U-Boot", for an ADM-XRC-7Z1 or ADM-XRC-7Z2.

Building Linux Kernel and Root File System

Required Tools

To follow this procedure you will require a PC or Virtual Machine running a Desktop Linux distribution. The system must be setup with the correct configuration before starting a build. See the The Linux Distribution' and The Build Host Packager's sections in http://www.yoctoproject.org 50 for instructions on setting up the required packages on your Linux Desktoo system.

Sources

After setting up a Linux desktop environment for the Yocto build system, **git** can be used to acquire the source code required. Start by creating a new directory for your Embedded Linux project. From inside the new directory use the following commands to acquire a cooles of the required code bases.

```
git clone -b fido git://git.yoctoproject.org/poky.git
git clone -b fido https://github.com/xliin/meta-xliinx.git
git clone -b fido https://github.com/openembedded/openembedded-core.git
git clone -b master https://github.com/adps/meta-adlnx.git
git clone -b master https://github.com/adps/meta-adlnx.git
git clone -b master https://github.com/adps/meta-adlnx.git
```

The last two code bases, meta-adinx and meta-admxrc7z, are Alpha Data's example root files system, and Alpha Data's board support package for the ADM-XRC-7Z1 and ADM-XRC-7Z2.

Building

From the ~/poky sub-folder in your Embedded Linux project directory, enter the following command to initialise the build environment:

source oe-init-build-env

This will create a build directory, **build**, which will be switched into to as the active directory after the script completes execution

Build setup

Before a build can be started, two files must be edited in the -/poky/build/conf directory; poky/build/conf/bblayers, and poky/build/conf/local.config

poky/build/conf/bblayers

The bblayers file must be modified to include the full path of additional layers that need to be added to the Yocto

Linux build system. Edit bilayers to be similar to the following, including the meta-adinx and meta-admxrc7z and layers and the openembedded-core/meta layer. Note the path /home/my_home/yocto_linux should be changed to the full path of your Embedded Linux project directory.

poky/build/conf/local.config

The local.config file must be modified to specify the target machine. Edit this file to include the following line to select the target machine:

```
machine ?= admxrc7z
```

Build

Use the following command in the ~/poky/build directory to start a build of the Embedded Linux Kernel and root file system. This will take some time to complete.

bitbake adlnx-image

The output should look similar to the following:

```
Build Configuration:
                = "1.26.0"
BB VERSION
BUILD SYS
                 = "x86 64-linux"
NATIVELSBSTRING = "openSUSE-project-13.2"
TARGET SYS
                = "arm-poky-linux-gnueabi"
                = "admyrc7z"
MACHINE
DISTRO
                 = "poky"
                 = "1.8"
DISTRO VERSION
TUNE FEATURES
                 = "arm armv7a vfp neon cortexa9"
TARGET FPU
                 = "vfp-neon"
```

/home/my home/yocto linux/poky/meta-yocto \

Building Linux for the ADMXRC7Z1/2 V1.0 - Mar 23, 2018

meta

meta-vocto = "fido:f366ff2c03885f0ac17415dfbc8f25b2b760b841" = "fido:cd3da9c95f48899e134a5b7ed1754fd18985df4f" meta

meta-xilinx = "fido:276717514962728501de0b69aee0d9052d9a1366"

meta-adlnx = "master:107fff621ea6ef730c9bc6644800a976cc66b482"

meta-admxrc7z = "master:a36ad52e7fb72fc30e43b9fe0b4259f22c8d4767"

NOTE: Preparing runqueue

NOTE: Executing SetScene Tasks NOTE: Executing RunQueue Tasks

Output files

After the build is completed, several output files are created in poky/build/tmp/deploy/images/admxrc7z/

ulmage-admxrc7z.bin

The Linux Yocto Poky Fido kernel image. This is the core of the operating system, but requires a device tree to provide details of the hardware configuration.

admyrc7z1 dth

Device tree blob. This provides details of the hardware configuration to the kernel.

adlnx-image-admxrc7z.cpio.gz.u-boot

The root file system as a RAM disk containing a CPIO image prepended with a Das U-Boot header.

Building a standalone toolchain

In addition to building the root file system and Kernel a standalone toolchain might be needed for developing application outside the Yocto environment. This can be build with the following command.

```
bitbake adlnx-image -c populate sdk
```

This will create the output file poky-glibc-x86_64-adlnx-image-cortexa9-vfp-neon-toolchain-1.8.sh. This is an installer created in pokyfbuild/tmpi/deploy/sdt/. Running this on a Linux system will allow the user to install cross compiler tools customised to target the adlnx reference image.

Emulation with QEMU

To build an image that will run on the QEMU virtual machine name in the local.conf file to **qemuzynq**. After modifying the local.conf file use **bitbake adinx-image** to build a kernel and root file system that will be compatable with the QEMU.

To run the QEMU with the built image execute the following command

runqemu qemuzynq nographic qemuparams="-m 512"

Das U-Boot

To make it easier to develop and update Embedded Linux images, the FSBL (First Stage Boot Loader) will load Das U-Boot. Das U-Boot is a second stage boot loader that allows a number of boot options, including booting from QSPI, SD card, and TFTP.

Sources

Acquire the sources to build Das U-Boot using the following command:

git clone -b master https://github.com/adps/u-boot-ad-zyng7.git

Building Das U-Boot

Execute the following commands inside the u-boot-ad-zvng7 directory:

To set up the system for cross-compiling, source the environment setup script that was generated when building the standalone toolchain

```
source /opt/pokv/1.8.2/environment-setup-cortexa9-vpf-neon-pokv-linux-gnueabi
source /opt/Xilinx/SDK/<SDK VERSION>/settings64.sh
export BUILD DIR=build
make admxrc7zl config
make all
```

Note: Running "make all" on some systems does not work, and instead you should run: make LDFLAGS="" CC="\$CC"

Output files

BOOT.bin

After building has completed, the following files can be found in the build directory:

u-boot elf This file is an ELF version of the built U-Boot binary.

This file is a bootable image containing both a basic FSBL for the ADM-XRC-7Z1 and the U-Boot binary.

Testing

The default environment variables in Das U-Boot will attempt to boot the admxrc7z1.bin kernel image with the adlnx-image-admxrc7z.cpio.gz.u-boot root file system and admxrc7z.dtb device tree.

Preparing an SDCard

connectors

To test the built Das U-Boot and Embedded Linux image, follow this procedure:

- 1 Prepare a micro SD card with a FAT32 primary active partition as the first partition.
- 2 Copy the following files into FAT32 partition of the micro SD card:
- ulmage-admxrc7z.bin, adlnx-image-admxrc7z.cpio.gz.u-boot, admxrc7z.dtb, BOOT.bin

 3 Configure the ADM-XRC-7Z1 for boot from uSD, by setting SW2-2 to On and SW2-1 to off.
- 4 With the ADM-XRC-7Z1 powered down, install the uSD card in the uSD card slot.
- 5 Depending on the carrier and break out board being used, connect a serial cable to the SO serial output from the ADM_XRC-771 See the User Manual for the ADM_XRC-771 for details of switches and
- 6 After powering on the ADM-XRC-7Z1 it should boot from the uSD card, first showing information about the ADM-XRC-7Z1 in the FSBL, before proceeding to load and execute U-Boot. U-Boot will wait for three seconds for a user to intervene before starting to load Embedded Linus.

After Linux has booted, the user name root can be used to log into the system (without a password).

Typical Boot Output

Extending and developing

Alpha Data's board support meta layer (meta-ad-zynq7) is only a basic example. If your FPGA design requires custom drivers and modifications to the device tree, the meta layer can be modified to include these.

Revision History

Revision	Date	Description of Change
1.0	11th August 2014	Initial draft
2.0	14th May 2015	Updated for using Fido Poky release.
2.1	23th Mar 2018	Minor corrections to file names.
